

C. Treasure Hunt in the Dungeon

Time Constraints

• **java** : 3.0 Seconds

Memory Constraints

• **java** : 509MB

You are an adventurer exploring an ancient dungeon filled with treasures. There are N treasures in a chamber, each having a weight and a value. You can carry at most W units of weight in your magical backpack. You must choose a subset of treasures such that:

- You do not exceed the total weight limit W
- You maximize the total value of the treasures you carry
- You may either take or skip each treasure -- no fractional taking

Your Task:

1. Compute the maximum total value you can carry.
2. Output the indices (1-based) of the treasures that must be taken to achieve this.

Input Format:

First line: Two integers N and W

$(1 \leq N \leq 1000, 1 \leq W \leq 10^5)$

Next N lines: Each line contains two integers $weight[i]$ and $value[i]$

$(1 \leq weight[i] \leq W, 0 \leq value[i] \leq 10^9)$

Sample Input

```
5 9
2 20
3 15
4 20
5 30
3 24
```

Sample Output

```
64
1 3 5
```
